
Course Project: Developing a DApp

Project Description

The default project consists in the development of a decentralized application (DApp) using smart contracts. The theme of the DApp can be chosen freely, but must not lead to a trivial implementation; consult the TA for theme suitability. It is recommended to use Solidity to write the required smart contracts and Truffle, Ganache, and Metamask for running the DApp; other languages and infrastructures can be used, but instructions need to be provided on how to run the DApp in this case. The project should be done in groups of two or three; grading standards will be the same in both cases.

Project Deliverables

The following items must be submitted to iCorsi by the 15th of December:

- Smart contracts source code;
- Off-chain source code;
- Brief, clear instructions on how to run and use the application if they differ from the standard npm, Truffle pipeline shown in class.
- Report describing the theme, implementation, and the challenges faced during development (max. 2 pages).

The project deliverables should be submitted by only one of the group members. The report should be in single column format with font size not smaller than 10pt, and should contain the name of all the group members.

Project Presentation

A 10 minutes presentation must be made on the week of the 18th of December. The presentation must describe the project goal and must contain a short live demo of the DApp. You can use prepared slides and the whiteboard during your presentation. All group members must participate in the presentation.

Grading

The project contributes to 25% of the final grade and will be graded in the following manner:

- 60% DApp functionality (relevance of the implementation and challenges solved);
- 20% Project report (contents and writing);
- 20% Project presentation (contents and presentation skill).
